

Package ‘smernc’

July 23, 2025

Type Package

Title Statistical Methods for Regional Counts

Version 1.8.4

Maintainer Joshua French <joshua.french@ucdenver.edu>

BugReports <https://github.com/jfrench/smerc/issues>

Description Implements statistical methods for analyzing the counts of areal data, with a focus on the detection of spatial clusters and clustering. The package has a heavy emphasis on spatial scan methods, which were first introduced by Kulldorff and Nagarwalla (1995) <[doi:10.1002/sim.4780140809](https://doi.org/10.1002/sim.4780140809)> and Kulldorff (1997) <[doi:10.1080/03610929708831995](https://doi.org/10.1080/03610929708831995)>.

bn.test	<i>Besag-Newell Test</i>
---------	--------------------------

Description

bn.test implements the Besag-Newell test of Besag and Newell (1991) for finding disease clusters.

Usage

```
bn.test(  
  coords,  
  cases,  
  pop,  
  cstar,  
  ex = sum(cases)/sum(pop) * pop,  
  alpha = 0.1,  
  longlat = FALSE,  
  modified = FALSE  
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
cstar	A non-negative integer indicating the minimum number of cases to include in each window.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
modified	A logical value indicating whether a modified version of the test should be performed. The original paper recommends computing the p-value for each cluster as $1 - \text{ppois}(cstar - 1, \text{lambda} = \text{expected})$. The modified version replaces cstar with cases, the observed number of cases in the region, and computes the p-value for the cluster as $1 - \text{ppois}(\text{cases} - 1, \text{lambda} = \text{ex})$. The default is modified = FALSE.

Value

Returns a smerc_cluster object.

Author(s)

Joshua French

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(x, y))
out <- bn.test(
  coords = coords, cases = nydf$cases,
  pop = nydf$pop, cstar = 6,
  alpha = 0.1
)
plot(out)

# better plotting
if (require("sf", quietly = TRUE)) {
  data(nysf)
  plot(st_geometry(nysf), col = color.clusters(out))
}
```

bn.zones

Determine case windows (circles)

Description

bn.zones determines the case windows (circles) for the Besag-Newell method.

Usage

```
bn.zones(d, cases, cstar)
```

```
casewin(d, cases, cstar)
```

Arguments

d	An $n \times n$ square distance matrix containing the intercentroid distance between the n region centroids.
cases	A vector of length n containing the observed number of cases for the n region centroids.
cstar	A non-negative integer indicating the minimum number of cases to include in each window.

Details

Using the distances provided in `d`, for each observation, the nearest neighbors are included in increasingly larger windows until at least `cstar` cases are included in the window. Each row of `d` is matched with the same position in `cases`.

Value

Returns the indices of the regions in each case window as a list. For each element of the list, the indices are ordered from nearest to farthest from each centroid (and include the starting region).

Author(s)

Joshua French

References

Besag, J. and Newell, J. (1991). The detection of clusters in rare diseases, *Journal of the Royal Statistical Society, Series A*, 154, 327-333.

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
d <- gedist(coords, longlat = FALSE)
cwins <- bn.zones(d, cases = nydf$cases, cstar = 6)
```

cepp.sim

Perform cepp.test on simulated data

Description

`cepp.sim` efficiently performs `cepp.test` on a simulated data set. The function is meant to be used internally by the `cepp.test` function, but is informative for better understanding the implementation of the test.

Usage

```
cepp.sim(nsim = 1, nn, ty, ex, wts, simdist = "multinomial")
```

Arguments

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>nn</code>	A list of nearest neighbors produced by <code>casewin</code> .
<code>ty</code>	The total number of cases in the study area.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>wts</code>	A list that has the weights associated with each region of each element of <code>nn</code> .
<code>simdist</code>	A character string indicating whether the simulated data should come from a "multinomial" or "poisson" distribution. The default is "multinomial", which fixes the total number of cases observed in each simulated data set.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
d <- gedist(as.matrix(coords), longlat = TRUE)
nn <- casewin(d, cases = nydf$pop, cstar = 15000)
cases <- floor(nydf$cases)
ty <- sum(cases)
ex <- ty / sum(nydf$pop) * nydf$pop
# find smallest windows with at least n* pop
nstar <- 1000
nn <- casewin(d, cases = nydf$pop, cstar = nstar)
# determine ts
wts <- cepp.weights(nn, nydf$pop, nstar)
tsim <- cepp.sim(1, nn = nn, ty = ty, ex = ex, wts = wts)
```

cepp.test

Cluster Evaluation Permutation Procedure Test

Description

`cepp.test` implements the Cluster Evaluation Permutation Procedure test of Turnbull et al. (1990) for finding disease clusters.

Usage

```
cepp.test(
  coords,
  cases,
  pop,
  nstar,
```

```

ex = sum(cases)/sum(pop) * pop,
nsim = 499,
alpha = 0.1,
longlat = FALSE,
simdist = "multinomial"
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
nstar	The size of the at-risk population in each window.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
simdist	A character string indicating whether the simulated data should come from a "multinomial" or "poisson" distribution. The default is "multinomial", which fixes the total number of cases observed in each simulated data set.

Value

Returns a `smerc_cluster` object.

  data(nysf)
  plot(st_geometry(nysf), col = color.clusters(out))
}
```

cepp.weights	<i>Compute region weights for cepp.test</i>
--------------	---

Description

Compute region weights for `cepp.test`

Usage

```
cepp.weights(nn, pop, nstar)
```

Arguments

<code>nn</code>	A list of nearest neighbors produced by <code>casewin</code> .
<code>pop</code>	The population size associated with each region.
<code>nstar</code>	The size of the at-risk population in each window.

Value

A list with elements related to the weight each nearest neighbor region will have in the corresponding weighted sum used to compute the test statistic

Examples

```
data(nydf)
coords <- with(nydf, cbind(x, y))
pop <- nydf$pop
# intercentroid distances
d <- gedist(coords)
```

```
# find smallest windows with cumulative population of
# at least n* = 1000
nn <- casewin(d, pop, 1000)
# compute weights
w <- cepp.weights(nn, pop, 1000)
```

clusters

Extract clusters

Description

clusters extracts the clusters contained in x.

Usage

```
clusters(x, idx = seq_along(x$clusters), ...)
```

Arguments

x	An object with clusters.
idx	An index vector indicating the elements of x\$clusters to print information for. The default is all clusters.
...	Currently unimplemented

Author(s)

Joshua French

Examples

```
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
out <- scan.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, nsim = 19,
  alpha = 0.2, longlat = TRUE
)
clusters(out)
clusters(out, idx = 1:2)
```

color.clusters	<i>Color clusters</i>
----------------	-----------------------

Description

color.clusters is a helper function to color clusters of regions produced by an appropriate method, e.g., scan.test or uls.test. Regions that are not part of any cluster have no color.

Usage

```
color.clusters(  
  x,  
  idx = seq_along(x$clusters),  
  col = grDevices::hcl.colors(length(idx))  
)
```

Arguments

x	An object of class scan produced by a function such as scan.test.
idx	An index vector indicating the elements of object\$clusters to print information for. The default is all clusters.
col	A vector of colors to color the clusters in x. Should have same length as the number of clusters in x.

Value

Returns a vector with colors for each region/centroid for the data set used to construct x.

Author(s)

Joshua French

Examples

```
set.seed(1)  
data(nydf)  
coords <- with(nydf, cbind(longitude, latitude))  
out <- scan.test(  
  coords = coords, cases = floor(nydf$cases),  
  pop = nydf$pop, alpha = 0.2, longlat = TRUE,  
  nsim = 9  
)  
#' # better plotting  
if (require("sf", quietly = TRUE)) {  
  data(nysf)  
  plot(st_geometry(nysf), col = color.clusters(out))  
  # plot only clusters 2 and 3  
  plot(st_geometry(nysf),
```

```

    col = color.clusters(out, idx = c(2, 3)),
    border = "white")
}

```

combine.zones *Combine distinct zones*

Description

combine.zones combines the elements of z1 and z2 into a single list, returning only the unique zones.

Usage

```
combine.zones(z1, z2)
```

Arguments

z1	A list of zones
z2	A list of zones

Value

A list of distinct zones

Examples

```

z1 <- list(1:2, 1:3)
z2 <- list(2:1, 1:4)
combine.zones(z1, z2)

```

csg2 *Construct connected subgraphs*

Description

csg2, lcsg2, and scsg2 construct connected subgraphs. These functions are not intended for users. nn contains a list of nearest neighbors for each region. idx is a vector of possible vertices being considered as a subgraph. w is a connectivity matrix relating the N vertices. $w[i, j] = 1$ if vertices i and j are connected, i.e., if they share an edge. The dimensions of w are $N \times k$, where $k = \text{length}(\text{idx})$. While the rows of w contain adjacency information for all N vertices, only the idx columns of the complete adjacency matrix are used in w. See Details for discussion of scsg.

Usage

```

csg2(cz, cnn, cw)

lcsg2(lcz, cnn, cw)

scsg2(
  nn,
  w,
  idx = seq_along(nn),
  nlevel = NULL,
  verbose = FALSE,
  logical = FALSE
)

```

Arguments

cz	A logical vector representing the current subgraph.
cnn	The indices of the neighbors of the current vertex.
cw	A binary adjacency matrix for the neighbors of the current vertex.
lcz	A list of current zones (in the form of logical vectors).
nn	A list of the nearest neighbors for each vertex (region).
w	A binary adjacency matrix indicating connected neighbors.
idx	A vector of vertices for which to construct the set of connected subgraphs.
nlevel	The maximum size of each subgraph.
verbose	A logical value indicating whether descriptive messages should be provided. Default is FALSE. If TRUE, this can be useful for diagnosing where the sequences of connected subgraphs is slowing down/having problems.
logical	A logical value indicating whether a list of logical vectors should be returned. The default is FALSE, indicating that the scsg function should return a list of vectors with each vector containing the vertex indices included in each subgraph.

Details

scsg2 performs a sequence of lcsg2 calls. Starting with `lcz == list(idx[1])`, scsg keeps iteratively building more connected subgraphs by performing something like: `lcz1 = list(idx[1])`, `lcz2 = lcsg2(lcz1, ...)`, `lcz3 = lcsg2(lcz2, ...)`. This is done until there are no more connected subgraphs among the elements of `idx`.

Value

A list with all possible connected subgraphs based on the user-provided parameters.

Examples

```
data(nydf)
data(nyw)
# determine 50 nn of region 1 for NY data
coords <- as.matrix(nydf[, c("longitude", "latitude")])
nn3 <- knn(coords, longlat = TRUE, k = 3)
z1 <- scsg2(nn3, nyw)
z2 <- flex.zones(coords, nyw, k = 3, longlat = TRUE)
all.equal(z1, z2)
```

dc.sim

Perform dc.test on simulated data

Description

dc.sim efficiently performs `dc.test` on a simulated data set. The function is meant to be used internally by the `dc.test` function, but is informative for better understanding the implementation of the test.

Usage

```
dc.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

Arguments

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The population upperbound (in total population) for a candidate zone.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```

data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
pop <- nydf$pop
ty <- sum(cases)
ex <- ty / sum(pop) * pop
d <- gedist(coords, longlat = TRUE)
nn <- nndist(d, ubd = 0.05)
max_pop <- sum(pop) * 0.25
tsim <- dc.sim(1, nn, ty, ex, nyw,
  pop = pop,
  max_pop = max_pop
)

```

dc.test

Double Connection spatial scan test

Description

dc.test implements the Double Connection spatial scan test of Costa et al. (2012). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic, with the added constraint that the region must have at least two connection (i.e., shares a border with) at least two of the regions in the current zone. This procedure is repeated until adding a connected region does not increase the test statistic (or the population or distance upper bounds are reached). The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Usage

```

dc.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Details

The maximum intercentroid distance can be found by executing the command: `gedist(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

Value

Returns a `smerc_cluster` object.

Author(s)

Joshua French

  data(nysf)
  plot(st_geometry(nysf), col = color.clusters(out))
}

```

dc.zones

*Determine zones for the Double Connected scan test***Description**

dc.zones determines the zones for the Double Connected scan test ([dc.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

Usage

```

dc.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.

ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

Details

Every zone considered must have a total population less than $ubpop * \text{sum}(\text{pop})$. Additionally, the maximum intercentroid distance for the regions within a zone must be no more than $ubd * \text{the maximum intercentroid distance across all regions}$.

Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

Costa, M.A. and Assuncao, R.M. and Kulldorff, M. (2012) Constrained spanning tree algorithms for irregularly-shaped spatial clustering, *Computational Statistics & Data Analysis*, 56(6), 1771-1783. <doi:10.1016/j.csda.2011.11.001>

Examples

```

data(nydf)
data(nyw)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
# find zone with max statistic starting from each individual region
all_zones <- dc.zones(coords,
  cases = floor(nydf$cases),
  nydf$pop, w = nyw, ubpop = 0.25,
  ubd = .25, longlat = TRUE
)

```

dist.ellipse	<i>Compute minor axis distance of ellipse</i>
--------------	---

Description

dist.ellipse computes the length of the minor axis needed for an ellipse of a certain shape and angle to intersect each of the other coordinates from a starting coordinate.

Usage

```
dist.ellipse(coords, shape, angle)
```

Arguments

coords	An $N \times 2$ matrix of coordinates
shape	The ratio of the major axis to the minor axis of the ellipse
angle	The angle of the ellipse in the range [0, 180).

Value

A matrix of distances between each coordinate and all other coordinates (and itself). Each row contains the distances for a coordinate.

Examples

```

data(nydf)
coords <- as.matrix(nydf[, c("x", "y")])
d <- dist.ellipse(coords, 4, 15)

```

`distinct`*Distinct elements of a list*

Description

`distinct` takes a list of integer vectors and returns the list indices that contain unique combinations of elements. This function is NOT robust against misuse, so please use properly.

Usage

```
distinct(x, N = max(unlist(x)))
```

Arguments

<code>x</code>	A list of integers
<code>N</code>	The largest integer value across all elements of <code>x</code> .

Details

Assume that `k` is the largest integer value in `x`. A vector of the largest `k` prime numbers is obtained (call this `pri`). The algorithm takes the sum of the log of `pri[x[[i]]]` for each element of `x`, and determines which sums are unique. This is why the elements of `x` must be integer vectors. The prime aspect of the algorithm is critical, as it ensures that a none of the values are multiples of the others, ensuring uniqueness.

Note: this algorithm has only been applied to data sets where each element of `x[[i]]` appears only once, though it should work for repeats also.

Value

A vector with the distinct indices.

Author(s)

Joshua French

References

Algorithm based on suggestion at <https://stackoverflow.com/a/29824978>.

Examples

```
x <- list(1:3, 3:1, 1:4, 4:1, c(1, 2, 4, 6), c(6, 4, 1, 2))
x[distinct(x)]
```

dmst.sim	<i>Perform dmst.test on simulated data</i>
----------	--

Description

dmst.sim efficiently performs `dmst.test` on a simulated data set. The function is meant to be used internally by the `dmst.test` function, but is informative for better understanding the implementation of the test.

Usage

```
dmst.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

Arguments

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>nn</code>	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
<code>ty</code>	The total number of cases in the study area.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>pop</code>	The population size associated with each region.
<code>max_pop</code>	The population upperbound (in total population) for a candidate zone.
<code>cl</code>	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
pop <- nydf$pop
ty <- sum(cases)
ex <- ty / sum(pop) * pop
d <- gedist(coords, longlat = TRUE)
nn <- nndist(d, ubd = 0.05)
max_pop <- sum(pop) * 0.25
tsim <- dmst.sim(1, nn, ty, ex, nyw,
  pop = pop,
  max_pop = max_pop
)
```

dmst.test

*Dynamic Minimum Spanning Tree spatial scan test***Description**

dmst.test implements the dynamic Minimum Spanning Tree scan test of Assuncao et al. (2006). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic. This procedure is repeated until the population or distance upper bounds are reached. The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Usage

```
dmst.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.

longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Details

The maximum intercentroid distance can be found by executing the command: `gedist(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

Value

Returns a `smerc_cluster` object.

dmst.zones *Determine zones for the Dynamic Minimum Spanning Tree scan test*

Description

dmst.zones determines the zones for the Dynamic Minimum Spanning Tree scan test ([dmst.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

Usage

```
dmst.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

Details

Every zone considered must have a total population less than $ubpop * \text{sum}(\text{pop})$. Additionally, the maximum intercentroid distance for the regions within a zone must be no more than $ubd * \text{the maximum intercentroid distance across all regions}$.

Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

 edmst.sim

Perform edmst.test on simulated data

Description

edmst.sim efficiently performs `edmst.test` on a simulated data set. The function is meant to be used internally by the `edmst.test` function, but is informative for better understanding the implementation of the test.

Usage

```
edmst.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

Arguments

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>nn</code>	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
<code>ty</code>	The total number of cases in the study area.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>pop</code>	The population size associated with each region.
<code>max_pop</code>	The population upperbound (in total population) for a candidate zone.
<code>cl</code>	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```

data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
pop <- nydf$pop
ty <- sum(cases)
ex <- ty / sum(pop) * pop
d <- gedist(coords, longlat = TRUE)
nn <- nndist(d, ubd = 0.05)
max_pop <- sum(pop) * 0.25
tsim <- edmst.sim(1, nn, ty, ex, nyw,
  pop = pop,
  max_pop = max_pop
)

```

edmst.test

Early Stopping Dynamic Minimum Spanning Tree spatial scan test

Description

`edmst.test` implements the early stopping dynamic Minimum Spanning Tree scan test of Costa et al. (2012). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic. This procedure is repeated until adding a connected region does not increase the test statistic (or the population or distance upper bounds are reached). The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Usage

```
edmst.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Details

The maximum intercentroid distance can be found by executing the command: `gedist(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

Value

Returns a `smerc_cluster` object.

edmst.zones

Determine zones for the early stopping dynamic Minimum Spanning Tree scan test

Description

edmst.zones determines the zones for the early stopping Dynamic Minimum Spanning Tree scan test ([edmst.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

Usage

```
edmst.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
```

```

    ubpop = 0.5,
    ubd = 1,
    longlat = FALSE,
    cl = NULL,
    progress = TRUE
  )

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

Details

Every zone considered must have a total population less than $ubpop * \text{sum}(\text{pop})$. Additionally, the maximum intercentroid distance for the regions within a zone must be no more than $ubd * \text{the maximum intercentroid distance across all regions}$.

Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

  nydf$pop, w = nyw, ubpop = 0.25,
  ubd = .25, longlat = TRUE
)
```

elbow_point

Compute Elbow Point

Description

elbow_point computes the elbow point based on the maximum distance between each point and the line passing through the end points.

Usage

```
elbow_point(x, y)
```

Arguments

x A numeric vector
y A numeric vector

Value

A list with the index (idx), x-value (x) and y-value (y) of the elbow point.

elbow_point(x, y)
```

elliptic.nn

*Nearest neighbors for elliptic scan***Description**

elliptic.nn computes the nearest neighbors relationships for elliptic.test. It will provide a list of nearest neighbors, and a list of the associated shape and angle.

Usage

```
elliptic.nn(
  coords,
  pop,
  ubpop = 0.5,
  shape = c(1, 1.5, 2, 3, 4, 5),
  nangle = c(1, 4, 6, 9, 12, 15)
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
shape	The ratios of the major and minor axes of the desired ellipses.
nangle	The number of angles (between 0 and 180) to consider for each shape.

Value

A list of nested nearest neighbors, the associated shapes and angles for each set of nn, and all of the shapes and angles you get for each zone constructed from the set of nearest neighbors.

Examples

```
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
enn <- elliptic.nn(coords, nydf$pop, 0.1,
  shape = c(1, 1.5), nangle = c(1, 4)
)
```

elliptic.penalty	<i>Compute elliptic penalty</i>
------------------	---------------------------------

Description

Compute eccentricity penalty for elliptic scan method.

Usage

```
elliptic.penalty(a, shape)
```

Arguments

a	Penalty scale
shape	Shape of ellipse.

Value

A vector of penalties

Examples

```
elliptic.penalty(a = 0.5, shape = c(1, 1.5, 2))
```

elliptic.sim.adj	<i>Perform elliptic.test on simulated data</i>
------------------	--

Description

elliptic.sim efficiently performs [elliptic.test](#) on a simulated data set. The function is meant to be used internally by the [elliptic.test](#) function, but is informative for better understanding the implementation of the test.

Usage

```
elliptic.sim.adj(
  nsim = 1,
  ex,
  nn,
  ty,
  logein,
  logeout,
  a,
  pen,
  min.cases = 2,
  cl = NULL
)
```

Arguments

nsim	A positive integer indicating the number of simulations to perform.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nn	A list of nearest neighbors produced by elliptic.nn .
ty	The total number of cases in the study area.
logein	The log of the expected number of cases in each candidate zone.
logeout	The log of the expected number of cases outside of each candidate zone.
a	The penalty for the spatial scan statistic. The default is 0.5.
pen	The eccentricity penalty for each candidate zone.
min.cases	The minimum number of cases required for a cluster. The default is 2.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
pop <- nydf$pop
enn <- elliptic.nn(coords, pop, ubpop = 0.5)
cases <- floor(nydf$cases)
ty <- sum(cases)
ex <- ty / sum(pop) * pop
yin <- nn.cumsum(enn$nn, cases)
ein <- nn.cumsum(enn$nn, ex)
```

```

logein <- log(ein)
logeout <- log(ty - ein)
pen <- elliptic.penalty(0.5, enn$shape_all)
tsim <- elliptic.sim.adj(
  nsim = 3, ex = ex,
  nn = enn$nn, ty = ty,
  logein = logein, logeout = logeout,
  a = 0.5, pen = pen
)

```

elliptic.test

Elliptical Spatial Scan Test

Description

elliptic.test performs the elliptical scan test of Kulldorf et al. (2006).

Usage

```

elliptic.test(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  shape = c(1, 1.5, 2, 3, 4, 5),
  nangle = c(1, 4, 6, 9, 12, 15),
  a = 0.5,
  cl = NULL,
  type = "poisson",
  min.cases = 2
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.

ubpop	The upperbound of the proportion of the total population to consider for a cluster.
shape	The ratios of the major and minor axes of the desired ellipses.
nangle	The number of angles (between 0 and 180) to consider for each shape.
a	The penalty for the spatial scan statistic. The default is 0.5.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
min.cases	The minimum number of cases required for a cluster. The default is 2.

Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. Candidate zones are elliptical and extend from the observed data locations. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Value

Returns a `smerc_cluster` object.

fast.sim

Perform fast.test on simulated data

Description

fast.sim efficiently performs [fast.test](#) on a simulated data set. The function is meant to be used internally by the [fast.test](#) function, but is informative for better understanding the implementation of the test.

Usage

```
fast.sim(nsim = 1, ty, ex, pop, ubpop, type = "poisson", cl = NULL)
```

Arguments

nsim	A positive integer indicating the number of simulations to perform.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```

data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
pop <- nydf$pop
ty <- sum(cases)
ex <- ty / sum(pop) * pop
tsim <- fast.sim(1, ty, ex, pop = pop, ubpop = 0.5)

```

fast.test

Fast Subset Scan Test

Description

fast.test performs the fast subset scan test of Neill (2012).

Usage

```

fast.test(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  longlat = FALSE,
  cl = NULL,
  type = "poisson"
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".

Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The windows are based on the Upper Level Sets proposed by Patil and Taillie (2004). The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Value

Returns a list of length two of class scan. The first element (clusters) is a list containing the significant, non-overlapping clusters, and has the following components:

locids	The location ids of regions in a significant cluster.
pop	The total population in the cluster window.
cases	The observed number of cases in the cluster window.
expected	The expected number of cases in the cluster window.
smr	Standardized mortality ratio (observed/expected) in the cluster window.
rr	Relative risk in the cluster window.
loglikrat	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
pvalue	The pvalue of the test statistic associated with the cluster window.

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

Examples

```

data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
out <- fast.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop,
  alpha = 0.05, longlat = TRUE,
  nsim = 49, ubpop = 0.5
)

```

fast.zones

Determine sequence of fast subset scan zones

Description

fast.zones determines the unique zones obtained by implementing the fast subset scan method of Neill (2012).

Usage

```
fast.zones(cases, pop, ubpop = 0.5, simple = TRUE)
```

Arguments

cases	The number of cases observed in each region.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
simple	A logical value indicating whether a simple version of the fast zones should be returned. See Details.

Details

The simple argument determines the formatting of the returned zones. If simple = TRUE, then a vector containing the sequential indices of the regions in each successive zones is returned. If simple = FALSE, then the complete list of all zones is returned (which is the standard format of most of the other *.zones functions).

The zones returned must have a total population less than ubpop * sum(pop) of all regions in the study area.

Value

Returns a vector of regions to sequentially and cumulatively consider for clustering.

Examples

```
data(nydf)
cases <- nydf$cases
pop <- nydf$pop
# compare output format
fast.zones(cases, pop, ubpop = 0.05)
fast.zones(cases, pop, ubpop = 0.05, simple = FALSE)
```

flex.sim

Perform flex.test on simulated data

Description

flex.sim efficiently performs `flex.test` on a simulated data set. The function is meant to be used internally by the `flex.test` function, but is informative for better understanding the implementation of the test.

Usage

```
flex.sim(
  nsim = 1,
  zones,
  ty,
  ex,
  type = "poisson",
  ein = NULL,
  eout = NULL,
  tpop = NULL,
  popin = NULL,
  popout = NULL,
  cl = NULL
)
```

Arguments

nsim	A positive integer indicating the number of simulations to perform.
zones	A list of zones to compute the test statistic over for each simulated data set.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.

type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be $ty - ein$ and is computed automatically if not provided.
tpop	The total population in the study area.
popin	The total population in the zone.
popout	The population outside the zone. This should be $tpop - popin$ and is computed automatically if not provided.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
zones <- flex.zones(coords, w = nyw, k = 3, longlat = TRUE)
cases <- floor(nydf$cases)
ty <- sum(cases)
ex <- ty / sum(nydf$pop) * nydf$pop
ein <- zones.sum(zones, ex)
tsim <- flex.sim(nsim = 2, zones, ty, ex, ein = ein, eout = ty - ein)
```

flex.test

Flexibly-shaped Spatial Scan Test

Description

`flex.test` performs the flexibly-shaped scan test of Tango and Takahashi (2005).

Usage

```
flex.test(
  coords,
  cases,
  pop,
  w,
```

```

    k = 10,
    ex = sum(cases)/sum(pop) * pop,
    type = "poisson",
    nsim = 499,
    alpha = 0.1,
    longlat = FALSE,
    cl = NULL,
    lonlat = longlat,
    ...
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
lonlat	Deprecated in favor of longlat.
...	Not used.

Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Value

Returns a list of length two of class scan. The first element (clusters) is a list containing the significant, non-overlapping clusters, and has the following components:

flex.zones

Determine zones for flexibly shaped spatial scan test

Description

flex.zones determines the unique zones to consider for the flexibly shaped spatial scan test of Tango and Takahashi (2005). The algorithm uses a breadth-first search to find all subgraphs connected to each vertex (region) in the data set of size k or less.

Usage

```
flex.zones(
  coords,
  w,
  k = 10,
  longlat = FALSE,
  cl = NULL,
```

```

    loop = FALSE,
    verbose = FALSE,
    pfreq = 1
  )

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
loop	A logical value indicating whether a loop should be used to implement the function instead of pbapply . The default is FALSE. If TRUE, then memory-saving steps are also taken.
verbose	A logical value indicating whether progress messages should be provided. The default is FALSE. If both loop and verbose are TRUE, informative messages are displayed that can be useful for diagnosing where the sequences of connected subgraphs are slowing down or having problems.
pfreq	The frequency that messages are reported from the loop (if verbose = TRUE). The default is pfreq = 1, meaning a message is returned for each index of the loop.

Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

flex_zones

*Determine zones for flexibly shaped spatial scan test***Description**

flex_zones determines the unique zones to consider for the flexibly shaped spatial scan test of Tango and Takahashi (2005). The algorithm uses a breadth-first search to find all subgraphs connected to each vertex (region) in the data set of size k or less.

Usage

```

flex_zones(
  coords,
  w,
  k = 10,
  longlat = FALSE,
  cl = NULL,
  loop = FALSE,
  verbose = FALSE,
  pfreq = 1
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	Ignored, but retained for backwards compatibility

loop	A logical value indicating whether a loop should be used to implement the function instead of <code>pbapply</code> . The default is FALSE. If TRUE, then memory-saving steps are also taken.
verbose	A logical value indicating whether progress messages should be provided. The default is FALSE. If both <code>loop</code> and <code>verbose</code> are TRUE, informative messages are displayed that can be useful for diagnosing where the sequences of connected subgraphs are slowing down or having problems.
pfreq	The frequency that messages are reported from the loop (if <code>verbose = TRUE</code>). The default is <code>pfreq = 1</code> , meaning a message is returned for each index of the loop.

Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

## End(Not run)
```

gedist

Compute distance for geographic coordinates

Description

`gedist` computes the distance between the coordinates in `x` and `y`. If `y` isn't supplied, then the distances are computed between the coordinates in `x` alone. Otherwise, the pairwise distances between the points in `x` and `y` are computed. If `longlat = TRUE`, then the great circle distance is computed. `euclidist` is a simplified version of `gedist` that computes Euclidean distances alone while `gcdist` is a simplified version of `gedist` that computes great circle distance alone.

Usage

```
gedist(x, y = NULL, longlat = FALSE)
```

```
euclidist(x, y = NULL)
```

```
gcdist(x, y = NULL)
```

Arguments

x	A two-dimensional matrix of coordinates.
y	A two-dimensional matrix of coordinates.
longlat	A logical value indicating whether Euclidean distance (longlat = FALSE) or great circle distance (longlat = TRUE) should be computed. The default is longlat = FALSE.

Details

The algorithm used when longlat = TRUE is a C++ port of the C code written by Roger Bivand for the spDists function in the sp package, which appears to be based on a special case of the Vincenty formula with a slight correction based on the WGS84 flattening constant. See https://en.wikipedia.org/wiki/Great-circle_distance.

Value

A matrix of distances

Examples

```
coords = matrix(runif(10), ncol = 2)
# euclidean distance
d = gedist(coords)
all.equal(d, as.matrix(dist(coords)),
          check.attributes = FALSE)
all.equal(gedist(coords), euclidist(coords))

# great circle distance
all.equal(gedist(coords, longlat = TRUE),
          gcdist(coords))
```

knn

K nearest neighbors

Description

knn returns the k nearest neighbors of the n coordinates in coords. The nearest neighbors are constructed to be self-inclusive, i.e., an observations is its closest neighbor.

Usage

```
knn(coords, longlat = FALSE, k = 1, d = NULL)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
d	An n by n distance matrix. If provided, this is used instead of computing d based on coords and longlat.

Value

An $n \times k$ matrix of nearest neighbors.

Examples

```
data(nydf)
coords <- nydf[, c("longitude", "latitude")]
knn(coords, longlat = TRUE, k = 4)
```

lget

Apply getElement over a list

Description

lget or lgetElement applies getElement to a list using [lapply](#). sget and sgetElement do the same thing with [sapply](#).

Usage

```
lget(X, name)

lgetElement(X, name)

sget(X, name, simplify = TRUE, USE.NAMES = TRUE)

sgetElement(X, name, simplify = TRUE, USE.NAMES = TRUE)
```

Arguments

<code>X</code>	A list.
<code>name</code>	a literal character string or a name (possibly backtick quoted). For extraction, this is normally (see under ‘Environments’) partially matched to the names of the object.
<code>simplify</code>	logical or character string; should the result be simplified to a vector, matrix or higher dimensional array if possible? For simplify it must be named and not abbreviated. The default value, TRUE, returns a vector or matrix if appropriate, whereas if <code>simplify = "array"</code> the result may be an array of “rank” (=length(dim(.))) one higher than the result of FUN(X[[i]]).
<code>USE.NAMES</code>	logical; if TRUE and if X is character, use X as names for the result unless it had names already. Since this argument follows . . . its name cannot be abbreviated.

Value

A list (`lget`) or vector (`sget`) of the same length as X with the name parts of each element of X.

Examples

```
e1 <- list(
  x = rnorm(5),
  y = letters[c(1:2, 2:1, 3)],
  z = c(TRUE, TRUE, FALSE, TRUE, TRUE)
)
e2 <- list(
  x = rnorm(5),
  y = letters[c(1:4, 1)],
  z = c(FALSE, TRUE, FALSE, TRUE, FALSE)
)
X <- list(e1, e2)
lget(X, name = "x")
sget(X, name = "y")
```

mlf.test

Maxima Likelihood First Scan Test

Description

`mlf.test` implements the Maxima Likelihood First scan test of Yao et al. (2011), which is actually a special case of the Dynamic Minimum Spanning Tree of Assuncao et al. (2006). Find the single region that maximizes the likelihood ratio test statistic. Starting with this single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the likelihood ratio test statistic. This procedure is repeated until the population and/or distance upper bound is reached.

Usage

```
mlf.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 0.5,
  longlat = FALSE,
  cl = NULL
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Details

Only a single candidate zone is ever returned because the algorithm only constructs a single sequence of starting zones, and overlapping zones are not returned. Only the zone that maximizes the likelihood ratio test statistic is returned.

Value

Returns a list of length two of class `scan`. The first element (`clusters`) is a list containing the significant, non-overlapping clusters, and has the following components:

<code>locids</code>	The location ids of regions in a significant cluster.
<code>pop</code>	The total population in the cluster window.
<code>cases</code>	The observed number of cases in the cluster window.
<code>expected</code>	The expected number of cases in the cluster window.
<code>smr</code>	Standardized mortality ratio (observed/expected) in the cluster window.
<code>rr</code>	Relative risk in the cluster window.
<code>loglikrat</code>	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
<code>pvalue</code>	The pvalue of the test statistic associated with the cluster window.
<code>w</code>	The adjacency matrix of the cluster.
<code>r</code>	The maximum radius of the cluster (in terms of intercentroid distance from the starting region).

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

)
plot(out)
```

mlf.zones

*Determine zones for the maxima likelihood first algorithm.***Description**

mlf.zones determines the most likely cluster zone obtained by implementing the maxima likelihood first scan method of Yao et al. (2011). Note that this is really just a special case of the dynamic minimum spanning tree (DMST) algorithm of Assuncao et al. (2006)

Usage

```
mlf.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.

Details

Each step of the mlf scan test seeks to maximize the likelihood ratio test statistic used in the original spatial scan test (Kulldorff 1997). The first zone considered is the region that maximizes this likelihood ration test statistic, providing that no more than ubpop proportion of the total population is in

the zone. The second zone is the first zone and the connected region that maximizes the scan statistic, subject to the population and distance constraints. This pattern continues until no additional zones can be added due to population or distance constraints.

Every zone considered must have a total population less than $ubpop * \text{sum}(\text{pop})$ in the study area. Additionally, the maximum intercentroid distance for the regions within a zone must be no more than $ubd * \text{the maximum intercentroid distance across all regions}$.

Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

Yao, Z., Tang, J., & Zhan, F. B. (2011). Detection of arbitrarily-shaped clusters using a neighbor-expanding approach: A case study on murine typhus in South Texas. *International Journal of Health Geographics*, 10(1), 1.

Examples

```
data(nydf)
data(nyw)
coords <- as.matrix(nydf[, c("x", "y")])
mlf.zones(coords,
  cases = floor(nydf$cases),
  pop = nydf$pop, w = nyw, longlat = TRUE
)
```

mlink.sim

Perform mlink.test on simulated data

Description

mlink.sim efficiently performs `mlink.test` on a simulated data set. The function is meant to be used internally by the `mlink.test` function, but is informative for better understanding the implementation of the test.

Usage

```
mlink.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

Arguments

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The population upperbound (in total population) for a candidate zone.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
pop <- nydf$pop
ty <- sum(cases)
ex <- ty / sum(pop) * pop
d <- gedist(coords, longlat = TRUE)
nn <- nndist(d, ubd = 0.05)
max_pop <- sum(pop) * 0.25
tsim <- mlink.sim(1, nn, ty, ex, nyw,
  pop = pop,
  max_pop = max_pop
)
```

Description

`mlink.test` implements the Maximum Linkage spatial scan test of Costa et al. (2012). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic, with the added constraint that the region has the maximum connections (i.e., shares a border with) with the regions in the current zone. This procedure is repeated until the population or distance upper bounds constraints are reached. The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Usage

```
mlink.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)
```

Arguments

<code>coords</code>	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
<code>cases</code>	The number of cases observed in each region.
<code>pop</code>	The population size associated with each region.
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>nsim</code>	The number of simulations from which to compute the p-value.
<code>alpha</code>	The significance level to determine whether a cluster is significant. Default is 0.10.
<code>ubpop</code>	The upperbound of the proportion of the total population to consider for a cluster.
<code>ubd</code>	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
<code>longlat</code>	The default is FALSE, which specifies that Euclidean distance should be used. If <code>longlat</code> is TRUE, then the great circle distance is used to calculate the intercentroid distance.

`cl` A cluster object created by [makeCluster](#), or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Details

The maximum intercentroid distance can be found by executing the command: `gedist(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

Value

Returns a `smerc_cluster` object.

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
out <- mlink.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, w = nyw,
  alpha = 0.12, longlat = TRUE,
  nsim = 2, ubpop = 0.05, ubd = 0.1
)
# better plotting
if (require("sf", quietly = TRUE)) {
  data(nysf)
  plot(st_geometry(nysf), col = color.clusters(out))
}
```

mlink.zones

*Determine zones for the Maximum Linkage scan test***Description**

mlink.zones determines the zones for the Maximum Linkage scan test ([mlink.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

Usage

```
mlink.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

Details

Every zone considered must have a total population less than $ubpop * \text{sum}(\text{pop})$. Additionally, the maximum intercentroid distance for the regions within a zone must be no more than $ubd * \text{the maximum intercentroid distance across all regions}$.

Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

Examples

```
data(nydf)
data(nyw)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
# find zone with max statistic starting from each individual region
all_zones <-mlink.zones(coords,
  cases = floor(nydf$cases),
  nydf$pop, w = nyw, ubpop = 0.25,
  ubd = .25, longlat = TRUE
)
```

morancr.sim

Constant-risk Moran's I statistic

Description

morancr.stat computes the constant-risk version of the Moran's I statistic proposed by Walter (1992).

Usage

```
morancr.sim(nsim = 1, cases, w, ex)
```

Arguments

nsim	The number of simulations from which to compute the p-value.
cases	The number of cases observed in each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.

Value

Returns a numeric value.

```

morancr.test

Constant-risk Moran's I-based test

Description

morancr.test performs a test of clustering using the constant-risk version of the Moran's I statistic proposed by Walter (1992) under the constant risk hypothesis.

Usage

```
morancr.test(
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alternative = "greater"
)
```

Arguments

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alternative	a character string specifying the alternative hypothesis, must be one of "greater" (default), "two.sided", or "less". You can specify just the initial letter.

Value

Returns a `smerc_similarity_test`.

```

mst.all

Minimum spanning tree for all regions

Description

`mst.all` finds the set of connected regions that maximize the spatial scan statistic (the likelihood ratio test statistic) from each starting region, subject to relevant constraints. The function can be used to construct candidate zones for the dynamic minimum spanning tree (`dmst`), early stopping dynamic minimum spanning tree (`edmst`), double connected spatial scan test (`dc`), and maximum linkage (`mmlink`) spatial scan test.

Usage

```
mst.all(
  neighbors,
  cases,
  pop,
  w,
  ex,
  ty,
  max_pop,
  type = "maxonly",
  nlinks = "one",
  early = FALSE,
  cl = NULL,
  progress = FALSE
)
```

Arguments

neighbors	A list containing the vector of neighbors for each region (in ascending order of distance from the region). The starting region itself is included among the neighbors.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ty	The total number of cases in the study area.
max_pop	The population upperbound (in total population) for a candidate zone.
type	One of "maxonly", "pruned", or "all". See Details.
nlinks	A character vector. The options are "one", "two", or "max". See Details.
early	A logical value indicating whether the "early" stopping criterion should be used. If TRUE, each sequence is stopped when the next potential zone doesn't produce a test statistic larger than the current zone. The default is FALSE.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

Details

This function is not intended to be used by users directly. Consequently, it prioritizes efficiency over user friendliness.

type is a character vector indicating what should be returned by the function. If type = "maxonly", then the maximum test statistic from each starting region is returned. If type = "pruned", the function returns a list that includes the location ids, test statistic, total cases, expected cases, and total population for the zone with the maximum test statistic for each starting region. If type = "all", the function returns a list of lists that includes the location ids, test statistic, total cases, expected cases, and total population for the sequence of candidate zones associated with each starting region.

If nlinks = "one", then a region only needs to be connected to one other region in the current zone to be considered for inclusion in the next zone. If nlinks = "two", then the region must be connected to at least two other regions in the current zone. If nlinks = "max", then only regions with the maximum number of connections to the current zone are considered for inclusion in the next zone.

Value

Returns a list of relevant information. See Details.

# upperbound for distance between centroids in zone
max_dist <- ubd * max(d)
# create list of neighbors for each region
```

```

# (inclusive of region itself)
all_neighbors <- nndist(d, ubd)
# find the dmst max zone
## Not run:
out <- mst.all(all_neighbors, cases, pop, w, ex, ty, max_pop,
  type = "maxonly"
)
head(out)

out <- mst.all(all_neighbors, cases, pop, w, ex, ty, max_pop,
  type = "pruned"
)
head(out)

## End(Not run)

```

mst.seq

Minimum spanning tree sequence

Description

mst.seq finds the sequence of connected regions that maximize the spatial scan statistic (the likelihood ratio test statistic) from a starting region. The set of connected regions at each step is a candidate zone. The zone continues to grow until no region should be added to the zone due to relevant constraints (size, connectivity, or other stopping criteria). This function is not intended to be used by users directly, but it can be quite educational for seeing the spread of the cluster. Consequently, it prioritizes efficiency over user friendliness.

Usage

```

mst.seq(
  start,
  neighbors,
  cases,
  pop,
  w,
  ex,
  ty,
  max_pop,
  type = "maxonly",
  nlinks = "one",
  early = FALSE
)

```

Arguments

start The initial region to start the candidate zone.

neighbors	A vector containing the neighbors for the starting region (in ascending order of distance from the region). The starting region itself is included among the neighbors.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ty	The total number of cases in the study area.
max_pop	The population upperbound (in total population) for a candidate zone.
type	One of "maxonly", "pruned", or "all". The default is "maxonly". See Details.
nlinks	A character vector. The options are "one", "two", or "max". See Details.
early	A logical value indicating whether the "early" stopping criterion should be used. If TRUE, the sequence is stopped when the next potential zone doesn't produce a test statistic larger than the current zone. The default is FALSE.

Details

The function can be used to construct candidate zones for the dynamic minimum spanning tree (dmst), early stopping dynamic minimum spanning tree (edmst), double connection spatial scan test (dc), and maximum linkage spatial scan test (mlink).

type is a character vector indicating what should be returned by the function. If type = "maxonly", then only the maximum of the log likelihood ratio test statistic across all candidate zones is returned. If type = "pruned", the function returns a list that includes the location ids, test statistic, total cases, expected cases, and total population for the zone with the maximum test statistic. If type = "all", the same information the same information is returned for the entire sequence of zones.

If nlinks = "one", then a region only needs to be connected to one other region in the current zone to be considered for inclusion in the next zone. If nlinks = "two", then the region must be connected to at least two other regions in the current zone. If nlinks = "max", then only regions with the maximum number of connections to the current zone are considered for inclusion in the next zone.

Value

Returns a list of relevant information. See Details.

  start = 1, all_neighbors[[1]], cases, pop,
  w, ex, ty, max_pop, "all"
)
head(bigout)

```

nclusters

Number of clusters

Description

nclusters returns the number of clusters identified in a smerc_cluster object.

Usage

```
nclusters(x)
```

Arguments

x A smerc_cluster object

Value

A non-negative integer.

Examples

```
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
out <- scan.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, nsim = 19,
  alpha = 0.3, longlat = TRUE
)
nclusters(out)
```

neast

Breast cancer mortality in the Northeastern United States

Description

An `sf` object containing data related to breast cancer mortality in the Northeastern United States. The data include several variables observed for 245 counties (or similar) as well polygon information defined using longitude/latitude coordinates in the WGS84 coordinate system. The following variables are included in the object:

- `id`: A name-based id for each county.
- `cases`: The number of breast cancer mortality cases between 1988-1992.
- `population`: The number of residents in the county based on 1990 U.S. census results.
- `x`: An x coordinate of a centroid associated with each county provided by Kulldorff et al. (2003). See Details.
- `y`: A y coordinate of a centroid associated with each county provided by Kulldorff et al. (2003). See Details.

Details

The `x` and `y` coordinates define centroids associated with each county. The coordinates were provided by Kulldorf et al. (2003). They are appropriate for computing standard Euclidean inter-centroid distance between counties but are not consistent with the polygon geometry of the data set. The coordinate system of these coordinates is unknown.

Alternative centroids for the geometry can be obtained using the following commands.

```
sf::sf_use_s2(FALSE)
pts <- sf::st_centroid(sf::st_geometry(neast))
```

```
if (require(sf)) {
  data(neast)
  plot(st_geometry(neast))
  plot(neast["cases"])
}
```

neastw	<i>Binary adjacency matrix for neast</i>
--------	--

Description

A binary adjacency matrix for the neast data set. Some of the islands (e.g., Nantucket) are considered adjacent to the mainland because of ferries traveling from certain mainland regions to these islands. Manual connections were added for many of the New York counties because they are on islands.

References

Martin Kulldorff, Eric J. Feuer, Barry A. Miller, Laurence S. Freedman; Breast Cancer Clusters in the Northeast United States: A Geographic Analysis, *American Journal of Epidemiology*, Volume 146, Issue 2, 15 July 1997, Pages 161–170. doi:[10.1093/oxfordjournals.aje.a009247](https://doi.org/10.1093/oxfordjournals.aje.a009247).

neast

nn.cumsum	<i>Cumulative sum over nearest neighbors</i>
-----------	--

Description

nn.cumsum computes the cumulative sum of y for the sequences of indices in each element of the list contained in nn.

Usage

```
nn.cumsum(nn, y, simplify = TRUE)
```

Arguments

nn	A list of nearest neighbors in the format produced by nnpop .
y	A numeric vector of values to be summed over.
simplify	A logical value indicating whether the results should be simplified to a numeric vector. The default is TRUE.

Value

A vector or list, depending on the value of `simplify`.

Examples

```
# show nn.cumsum example for a circular scan setting
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
d <- gedist(coords, longlat = TRUE)
# compute circular nearest neighbors
nn <- nnpop(d, pop = nydf$pop, ubpop = 0.1)
# compute cumulative sums over all nn
cnn <- nn.cumsum(nn, cases)
# compute cumulative sums over just the first set of nn
cnn1 <- cumsum(cases[nn[[1]]])
# check equality
all.equal(cnn1, cnn[seq_along(cnn1)])
```

nn2zones

Convert nearest neighbors list to zones

Description

nn2zones converts a list of nearest neighbors to a list of zones. The list of nearest neighbors will come from functions such as `nnpop` or `knn`.

Usage

```
nn2zones(nn)
```

Arguments

nn A list of nearest neighbors

Value

A list of zones

Examples

```
data(nydf)
coords <- with(nydf, cbind(x, y))
nn <- knn(coords, k = 2)
nn2zones(nn)
```

nndist	<i>Determine nearest neighbors based on maximum distance</i>
--------	--

Description

nndist determines the nearest neighbors for a set of observations within a certain radius.

Usage

```
nndist(d, ubd)
```

Arguments

d	An $n \times n$ square distance matrix containing the intercentroid distance between the n region centroids.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$, where m is the maximum intercentroid distance between all coordinates.

Details

This function determines the nearest neighbors of each centroid based on the intercentroid distance. The number of nearest neighbors is limited by the furthest distance between the starting centroid and the farthest neighbor.

Value

Returns the indices of the nearest neighbors as a list.

Author(s)

Joshua French

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
d <- as.matrix(dist(coords))
nn <- nndist(d, ubd = 0.01)
```

nndup	<i>Determine duplicates in nearest neighbor list</i>
-------	--

Description

nndup determines the indices of duplicated elements for a nearest neighbors list created by a function such as `nnpop` or `knn`. The indices are related to the list returned by `nn2zones`.

Usage

```
nndup(nn, N = max(unlist(nn)))
```

Arguments

nn	A list of nearest neighbors.
N	The largest value in nn.

Value

A logical vector of indicating duplicate indices.

Examples

```
nn <- list(1:3, c(2:1, 4))
nndup(nn, 4)
```

nnpop	<i>Determine nearest neighbors with population constraint</i>
-------	---

Description

`scan.nn` determines the nearest neighbors for a set of observations based on the distance matrix according to a population-based upperbound.

Usage

```
nnpop(d, pop, ubpop)

scan.nn(d, pop, ubpop)
```

Arguments

d	An $n \times n$ square distance matrix containing the intercentroid distance between the n region centroids.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

Details

This function determines the nearest neighbors of each centroid based on the intercentroid distance. The number of nearest neighbors is limited by the sum of the population values among the nearest neighbors. The set of nearest neighbors can contain no more than $ubpop * \text{sum}(\text{pop})$ members of the population. The nearest neighbors are ordered from nearest to farthest.

Value

Returns the indices of the nearest neighbors as a list. For each element of the list, the indices are ordered from nearest to farthest from each centroid.

Author(s)

Joshua French

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
d <- as.matrix(dist(coords))
nn <- scan.nn(d, pop = nydf$pop, ubpop = 0.1)
```

noz

Determine non-overlapping zones

Description

Determine non-overlapping zones from a list of candidate zones.

Usage

```
noz(x)
```

Arguments

x A list containing the candidate zones.

Details

The function takes a list of candidate zones. Each element of the list contains a candidate zones. The candidate zones are defined by the location indices of the regions comprising the zones. Starting with the first candidate zone, the function excludes every candidate zone that intersects the first (any other candidate zone that shares indices with the first zone). Moving onto the next non-overlapping candidate zone, the process is repeated. The function returns the indices (in the list of zones) of the zones that do not overlap.

Value

A vector with the list indices of the non-overlapping zones.

Author(s)

Joshua French

Examples

```
x <- list(1:2, 1:3, 4:5, 4:6, 7:8)
noz(x)
```

nydf

Leukemia data for 281 regions in New York.

Description

This data set contains 281 observations related to leukemia cases in an 8 county area of the state of New York. The data were made available in Waller and Gotway (2005) and details are provided there. These data are related to a similar data set in Waller et al. (1994). The longitude and latitude coordinates are taken from the NYleukemia data set in the SpatialEpi package for plotting purposes.

Usage

```
data(nydf)
```

Format

A data frame with 281 rows and 4 columns:

longitude The longitude of the region centroid. These are NOT the original values provided by Waller and Gotway (2005), but are the right ones for plotting correctly.

latitude The latitude of the region centroid. These are NOT the original values provided by Waller and Gotway (2005), but are the right ones for plotting correctly.

population The population (1980 census) of the region.

cases The number of leukemia cases between 1978-1982.

x The original 'longitude' coordinate provided by Waller and Gotway (2005).

y The original 'latitude' coordinate provided by Waller and Gotway (2005).

nypoly	SpatialPolygons <i>object for New York leukemia data.</i>
--------	---

Description

A SpatialPolygons object for the New York leukemia data in nydf. Note that the coordinates in the polygon have been projected to a different coordinate system (UTM, zone 18), but the order of the regions/polygons is the same as in nydf.

Usage

```
data(nypoly)
```

Format

A SpatialPolygonDataFrame

Source

Bivand, R. S., Pebesma, E. J., Gomez-Rubio, V., and Pebesma, E. J. (2013). Applied Spatial Data Analysis with R, 2nd edition. New York: Springer.

nysf	sf <i>object for New York leukemia data.</i>
------	--

Description

The number of incident leukemia cases from 1978-1982 per census tract for an 8-county region of upstate New York.

This is the same data as in nydf in a different format.

Note that the coordinates in the polygons have been projected to a different coordinate system (UTM, zone 18) compared to nydf, but the order of the regions/polygons is the same as in nydf.

Usage

```
data(nysf)
```

Format

A sf with 281 rows and 18 columns:

areaname The name of the region.

areakey Census tract id.

xorig x-coordinate associated with the centroid of each region on the ORIGINAL scale.

yirug y-coordinate associated with the centroid of each region on the ORIGINAL scale.

pop8 The population (1980 census) of the region.

tractcas The number of leukemia cases between 1978-1982, rounded to two decimal places.

propcas The proportion of cases relative to population.

pctownhome The percentage of homeowners in the tract.

pctage65p The percentage of residents aged 65 or older.

Z A transformation of exposure to TCE, specifically $\log(1000(\text{TCE} + 1)/\text{pop8})$.

avgdist Average inverse distance to the nearest TCE site.

pexposure

cases The number of leukemia cases between 1978-1982.

xm A shifted version of x.

ym A shifted version of y.

x x-coordinate associated with the centroid of each region.

y y-coordinate associated with the centroid of each region.

geometry The geometry list column of the object.

Source

Bivand, R. S., Pebesma, E. J., Gomez-Rubio, V., and Pebesma, E. J. (2013). Applied Spatial Data Analysis with R, 2nd edition. New York: Springer.

nysp

SpatialPolygonsDataFrame for New York leukemia data.

Description

A `SpatialPolygonsDataFrame` object containing New York leukemia data. Methods for `SpatialPolygonsDataFrame` are provided by the `sp` package, which must be loaded to make full use of this data format.

The number of incident leukemia cases from 1978-1982 per census tract for an 8-county region of upstate New York.

This is the same data as in `nydf` in a different format.

Note that the coordinates in the polygons have been projected to a different coordinate system (UTM, zone 18) compared to `nydf`, but the order of the regions/polygons is the same as in `nydf`.

Usage

```
data(nysp)
```

Format

A SpatialPolygonsDataFrame with 281 rows and 17 columns:

areaname The name of the region.

areakey Census tract id.

xorig x-coordinate associated with the centroid of each region on the ORIGINAL scale.

yirug y-coordinate associated with the centroid of each region on the ORIGINAL scale.

pop8 The population (1980 census) of the region.

tractcas The number of leukemia cases between 1978-1982, rounded to two decimal places.

propcas The proportion of cases relative to population.

pctownhome The percentage of homeowners in the tract.

pctage65p The percentage of residents aged 65 or older.

Z A transformation of exposure to TCE, specifically $\log(1000(\text{TCE} + 1)/\text{pop8})$.

avgidist Average inverse distance to the nearest TCE site.

pexposure

cases The number of leukemia cases between 1978-1982.

xm A shifted version of x.

ym A shifted version of y.

x x-coordinate associated with the centroid of each region.

y y-coordinate associated with the centroid of each region.

 nyw

Adjacency matrix for New York leukemia data.

Description

This data set contains a 281 x 281 adjacency matrix for the New York leukemia data in nydf.

Usage

`data(nyw)`

Format

A matrix of dimension 281 x 281.

Source

Waller, L.A. and Gotway, C.A. (2005). Applied Spatial Statistics for Public Health Data. Hoboken, NJ: Wiley.

References

 optimal_ubpop

Optimal Population Upper Bound Statistics

Description

optimal_ubpop computes statistics for choosing an optimal population upper bound. ubpop_seq is a sequence of values to consider as the optimal choice of upper bound. The smallest value must be at least $\min(\text{pop})/\text{sum}(\text{pop})$ and should generally be less than or equal to 0.5.

Usage

```
optimal_ubpop(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.05,
  ubpop_seq = seq(0.01, 0.5, len = 50),
  longlat = FALSE,
  cl = NULL,
  type = "poisson",
  min.cases = 0,
  simdist = "multinomial"
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.

alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop_seq	A strictly increasing numeric vector with values between min(pop)/sum(pop) and 1. The default is seq(0.01, 0.5, len = 50).
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
min.cases	The minimum number of cases required for a cluster. The default is 2.
simdist	Character string indicating the simulation distribution. The default is "multinomial", which conditions on the total number of cases observed. The other options are "poisson" and "binomial"

Value

Returns a `smerc_optimal_ubpop` object. This includes:

ubpop_seq	The sequence of population bounds considered
elbow_method	An object with statistics related to the elbow method
gini_method	An object with statistics related to the gini method
elbow_ubpop	The population upperbound suggested by the elbow method
gini_ubpop	The population upperbound suggested by the Gini method

[scan.test](#)

Examples

```

data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
ubpop_stats <- optimal_ubpop(
  coords = coords, cases = nydf$cases,
  pop = nydf$pop, nsim = 49,
  ubpop_seq = seq(0.05, 0.5, by = 0.05)
)
ubpop_stats
## Not run:
plot(ubpop_stats)

## End(Not run)

```

plot.smerc_cluster *Plot object of class smerc_cluster.*

Description

Plot clusters (the centroids of the regions in each cluster) in different colors. The most likely cluster is plotted with solid red circles by default. Points not in a cluster are black open circles. The other cluster points are plotted with different symbols and colors.

Usage

```

## S3 method for class 'smerc_cluster'
plot(
  x,
  ...,
  idx = seq_along(x$clusters),
  nclusters = NULL,
  ccol = NULL,
  cpch = NULL,
  add = FALSE,
  usemap = FALSE,
  mapargs = list()
)

```

Arguments

x	An object of class scan to be plotted.
...	Additional graphical parameters passed to the plot function.
idx	An index vector indicating the elements of x\$clusters to print information for. The default is all clusters.
nclusters	Number of clusters to plot. Deprecated. Use idx.
ccol	Fill color of the plotted points. Default is grDevices::hcl.colors(nclusters, palette = "viridis").

cpch	Plotting character to use for points in each cluster. Default is NULL, indicating pch = 20 for the most likely cluster and then pch = 2, 3, ..., up to the remaining number of clusters.
add	A logical indicating whether results should be drawn on existing map.
usemap	Logical indicating whether the maps::map function should be used to create a plot background for the coordinates. Default is FALSE. Use TRUE if you have longitude/latitude coordinates.
mapargs	A list of arguments for the map function.

Examples

```

data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
out <- scan.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, nsim = 0,
  longlat = TRUE, alpha = 1
)
# plot only 3 most likely clusters
plot(out, idx = 1:3)
## plot output for new york state
# specify desired argument values
mapargs <- list(
  database = "county", region = "new york",
  xlim = range(out$coords[, 1]),
  ylim = range(out$coords[, 2])
)
# needed for "county" database (unless you execute library(maps))
data(countyMapEnv, package = "maps")
# plot only the 1st and 3rd clusters
plot(out, idx = 1:3, usemap = TRUE, mapargs = mapargs)

```

```
plot.smerc_optimal_ubpop
```

Plot object of class smerc_optimal_ubpop.

Description

Plot results of [optimal_ubpop](#). This is only meant for a visual summary of the results. Users will need to access the elements of the `smerc_optimal_ubpop` object `x` if they want to create a custom plot.

Usage

```

## S3 method for class 'smerc_optimal_ubpop'
plot(x, ..., method = "all")

```

Arguments

x	An object of class <code>smerc_optimal_ubpop</code> .
...	Not used
method	The method to plot. The default is "all". The other valid options are "elbow" and "gini".

See Also

[optimal_ubpop](#)

Examples

```

data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
ubpop_stats <- optimal_ubpop(
  coords = coords, cases = nydf$cases,
  pop = nydf$pop, nsim = 49,
  ubpop = seq(0.05, 0.5, by = 0.05)
)
## Not run:
plot(ubpop_stats)

## End(Not run)
plot(ubpop_stats, method = "elbow")
plot(ubpop_stats$ubpop_seq, ubpop_stats$elbow_method$stats)
plot(ubpop_stats, method = "gini")
plot(ubpop_stats$ubpop_seq, ubpop_stats$gini_method$stats)

```

plot.tango

Plots an object of class tango.

Description

Plots results of [tango.test](#). If Monte Carlo simulation was not used to produce `x`, then a density plot of the (approximate) null distribution of `tstat.chisq` is produced, along with a vertical line for the observed `tstat`. If a Monte Carlo test was used to produce `x`, then a scatterplot of the `gof.sim` versus `sa.sim` is compared to the observed values `gof` and `sa`, respectively.

Usage

```

## S3 method for class 'tango'
plot(x, ..., obs.list = list(pch = 20), sim.list = list(pch = 2))

```

Arguments

<code>x</code>	An object of class <code>tango</code> to be plotted.
<code>...</code>	Additional graphical parameters passed to <code>plot</code> function.
<code>obs.list</code>	A list containing arguments for the <code>points</code> function, which is used to plot the <code>gof</code> and <code>sa</code> components, when appropriate.
<code>sim.list</code>	A list containing arguments for the <code>points</code> function, which is used to plot the <code>gof.sim</code> and <code>sa.sim</code> components, when appropriate.

See Also

[tango.test](#)

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("x", "y")])
w <- dweights(coords, kappa = 1)
x1 <- tango.test(nydf$cases, nydf$pop, w)
plot(x1)
x2 <- tango.test(nydf$cases, nydf$pop, w, nsim = 49)
plot(x2)
```

```
precog.sim
```

Perform precog.test on simulated data.

Description

`precog.sim` efficiently performs [precog.test](#) on a simulated data set. The function is meant to be used internally by the [precog.test](#) function, but is informative for better understanding the implementation of the test.

Usage

```
precog.sim(
  nsim = 1,
  zones,
  ty,
  ex,
  w,
  pop,
  max_pop,
  logein,
  logeout,
  d,
  cl = NULL,
  tol_prob = 0.9,
  ysim = NULL
)
```

Arguments

nsim	The number of simulations from which to compute the p-value.
zones	A list with of candidate zones that includes each regions and its adjacent neighbors.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The maximum population size allowable for a cluster.
logein	The log of the expected number of cases in each candidate zone.
logout	The log of the expected number of cases outside of each candidate zone.
d	A precomputed distance matrix based on coords
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
tol_prob	A single numeric value between 0 and 1 that describes the quantile of the tolerance envelopes used to prefilter regions from the candidate zones.
ysim	A matrix of size $nsim \times n$, where n is the number of regions in the study area. This is a matrix of $nsim$ realizations of the case counts for each region in the study area under the null hypothesis. This argument is only not meant to be used by the user.

Value

A list with the vector of tolerance quantiles associated with each region and a vector with the maximum test statistic for each simulated data set.

Author(s)

Joshua French and Mohammad Meysami

```
precog.test
```

```
PreCoG Scan Test
```

Description

precog.test is an implementation of the Prefiltered Component-based Greedy Scan Method.

Usage

```
precog.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  tol_prob = 0.9,
  alpha = 0.1,
  ubpop = 0.5,
  longlat = FALSE,
  cl = NULL,
  ysim = NULL
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
tol_prob	A single numeric value between 0 and 1 that describes the quantile of the tolerance envelopes used to prefilter regions from the candidate zones.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
ysim	A matrix of size $nsim \times n$, where n is the number of regions in the study area. This is a matrix of $nsim$ realizations of the case counts for each region in the study area under the null hypothesis. This argument is only not meant to be used by the user.

Value

Returns a `smerc_cluster` object.

Author(s)

Joshua French and Mohammad Meysami

Examples

```
data(nydf)
data(nyw)
out <- precog.test(coords = nydf[,c("x", "y")],
                  cases = floor(nydf$cases),
                  pop = nydf$pop, w = nyw, nsim = 19,
                  alpha = 0.2)
# better plotting
if (require("sf", quietly = TRUE)) {
  data(nysf)
  plot(st_geometry(nysf), col = color.clusters(out))
}
```

`print.smerc_cluster` *Print object of class `smerc_cluster`.*

Description

Print `smerc_cluster` object

Usage

```
## S3 method for class 'smerc_cluster'
print(x, ..., extra = FALSE)
```

Arguments

<code>x</code>	An object of class <code>smerc_cluster</code> .
<code>...</code>	Not currently implemented.
<code>extra</code>	A logical value. Default is <code>FALSE</code> . <code>TRUE</code> indicates that extra information should be printed.

Examples

```
data(nydf)
coords <- with(nydf, cbind(x, y))
out <- scan.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, nsim = 49,
  longlat = TRUE, alpha = 0.12
)
out
```

```
print.smerc_optimal_ubpop
```

Print object of class smerc_optimal_ubpop.

Description

Print smerc_optimal_ubpop object

Usage

```
## S3 method for class 'smerc_optimal_ubpop'
print(x, ...)
```

Arguments

x	An object of class smerc_optimal_ubpop.
...	Not currently implemented.

Examples

```
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
ubpop_stats <- optimal_ubpop(
  coords = coords, cases = nydf$cases,
  pop = nydf$pop, nsim = 49,
  ubpop = seq(0.05, 0.5, by = 0.05)
)
ubpop_stats
```

```
print.smerc_similarity_test
      Print object of class smerc_similarity_test.
```

Description

Print a smerc_similarity_test object. If the crayon package is installed, then the results are printed in color.

Usage

```
## S3 method for class 'smerc_similarity_test'
print(x, ..., digits = 2)
```

Arguments

x	An object of class smerc_similarity+test.
...	Not currently implemented.
digits	Number of significant digits to print.

```
print.tango      Print object of class tango.
```

Description

Print a tango object. If the crayon package is installed, then the results are printed in color.

Usage

```
## S3 method for class 'tango'
print(x, ..., digits = 2)
```

Arguments

x	An object of class tango.
...	Not currently implemented.
digits	Number of significant digits to print.

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("x", "y")])
w <- dweights(coords, kappa = 1)
results <- tango.test(nydf$cases, nydf$pop, w, nsim = 49)
results
```

rflex.midp	<i>Compute middle p-value</i>
------------	-------------------------------

Description

Computes $P(Y > \text{cases}) + P(Y = \text{cases})/2$ when $Y \sim \text{Poisson}(\text{ex})$ or $Y \sim \text{Binomial}(n = \text{pop}, p = \text{ex}/\text{pop})$. This is middle p-value computed by Tango and Takahashi (2012).

Usage

```
rflex.midp(cases, ex, type = "poisson", pop = NULL)
```

Arguments

cases	The number of cases observed in each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
pop	The population size associated with each region.

Value

A vector of middle p-values

Author(s)

Joshua French

References

Tango, T. and Takahashi, K. (2012), A flexible spatial scan statistic with a restricted likelihood ratio for detecting disease clusters. *Statist. Med.*, 31: 4207-4218. <doi:10.1002/sim.5478>

Examples

```
data(nydf)
cases <- floor(nydf$cases)
pop <- nydf$pop
ex <- pop * sum(cases) / sum(pop)
# zones for poisson model
pp <- rflex.midp(cases, ex)
# zones for binomial model
bp <- rflex.midp(cases, ex, type = "binomial", pop = pop)
```

`rflex.sim`*Perform rflex.test on simulated data*

Description

`rflex.sim` efficiently performs `rflex.test` on a simulated data set. The function is meant to be used internally by the `rflex.test` function, but is informative for better understanding the implementation of the test.

Usage

```
rflex.sim(  
  nsim = 1,  
  nn,  
  w,  
  ex,  
  alpha1 = 0.2,  
  type = "poisson",  
  pop = NULL,  
  cl = NULL  
)
```

Arguments

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>nn</code>	A matrix of the k nearest neighbors for the regions described by <code>w</code> .
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>alpha1</code>	The middle p-value threshold.
<code>type</code>	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
<code>pop</code>	The population size associated with each region.
<code>cl</code>	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```

data(nydf)
data(nyw)
# determine knn
coords <- with(nydf, cbind(longitude, latitude))
nn <- knn(coords, longlat = TRUE, k = 50)
# determine expected number of cases in each region
cases <- floor(nydf$cases)
pop <- nydf$pop
ex <- pop * sum(cases) / sum(pop)
tsim <- rflex.sim(nsim = 5, nn = nn, w = nyw, ex = ex)

```

rflex.test

Restricted Flexibly-shaped Spatial Scan Test

Description

rflex.test performs the restricted flexibly shaped spatial scan test of Tango and Takahashi (2012).

Usage

```

rflex.test(
  coords,
  cases,
  pop,
  w,
  k = 50,
  ex = sum(cases)/sum(pop) * pop,
  type = "poisson",
  nsim = 499,
  alpha = 0.1,
  longlat = FALSE,
  alpha1 = 0.2,
  cl = NULL
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10

ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
alpha1	The middle p-value threshold.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Value

Returns a list of length two of class scan. The first element (clusters) is a list containing the significant, non-overlapping clusters, and has the following components:

coords	The centroid of the significant clusters.
r	The radius of the window of the clusters.
pop	The total population in the cluster window.
cases	The observed number of cases in the cluster window.
expected	The expected number of cases in the cluster window.
smr	Standardized mortality ratio (observed/expected) in the cluster window.
rr	Relative risk in the cluster window.
loglikrat	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
pvalue	The pvalue of the test statistic associated with the cluster window.

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

rflex.zones

Determine zones for flexibly shaped spatial scan test

Description

rflex.zones determines the unique zones to consider for the flexibly shaped spatial scan test of Tango and Takahashi (2012). The algorithm uses a breadth-first search to find all subgraphs connected to each vertex (region) in the data set of size k or less with the constraint that the middle p -value of each region must be less than α .

Usage

```
rflex.zones(
  nn,
  w,
  cases,
  ex,
  alpha1 = 0.2,
  type = "poisson",
  pop = NULL,
  cl = NULL,
  loop = FALSE,
  verbose = FALSE,
  pfreq = 1
)
```

Arguments

nn	An n by k matrix providing the k nearest neighbors of each region, presumably produced by the knn function.
w	A binary spatial adjacency matrix for the regions.
cases	The number of cases observed in each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
alpha1	The middle p-value threshold.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
pop	The population size associated with each region. The default is NULL since this argument is only needed for type = "binomial".
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
loop	A logical value indicating whether a loop should be used to implement the function instead of pbapply . The default is FALSE. If TRUE, then memory-saving steps are also taken.
verbose	A logical value indicating whether progress messages should be provided. The default is FALSE. If both loop and verbose are TRUE, informative messages are displayed that can be useful for diagnosing where the sequences of connected subgraphs are slowing down or having problems.
pfreq	The frequency that messages are reported from the loop (if verbose = TRUE). The default is pfreq = 1, meaning a message is returned for each index of the loop.

Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

scan.sim.adj

Perform scan.test on simulated data

Description

scan.sim efficiently performs [scan.test](#) on a simulated data set. The function is meant to be used internally by the [scan.test](#) function, but is informative for better understanding the implementation of the test.

Usage

```

scan.sim.adj(
  nsim = 1,
  nn,
  ty,
  ex,
  type = "poisson",
  logein = NULL,
  logeout = NULL,
  tpop = NULL,
  popin = NULL,
  popout = NULL,
  logpopin = NULL,
  logpopout = NULL,
  cl = NULL,

```

```

  simdist = "multinomial",
  pop = NULL,
  min.cases = 2
)

```

Arguments

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of nearest neighbors produced by nnpop .
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
logein	The log of the expected number of cases in each candidate zone.
logeout	The log of the expected number of cases outside of each candidate zone.
tpop	The total population in the study area.
popin	The total population in the zone.
popout	The population outside the zone. This should be tpop - popin and is computed automatically if not provided.
logpopin	The log of the population in each candidate zone.
logpopout	The log of the population outside of each candidate zone.
cl	A cluster object created by makeCluster , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
simdist	Character string indicating the simulation distribution. The default is "multinomial", which conditions on the total number of cases observed. The other options are "poisson" and "binomial"
pop	The population size associated with each region.
min.cases	The minimum number of cases required for a cluster. The default is 2.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```

data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
d <- gedist(as.matrix(coords), longlat = TRUE)
nn <- scan.nn(d, pop = nydf$pop, ubpop = 0.1)
cases <- floor(nydf$cases)
ty <- sum(cases)
ex <- ty / sum(nydf$pop) * nydf$pop

```

```

yin <- nn.cumsum(nn, cases)
ein <- nn.cumsum(nn, ex)
tsim <- scan.sim.adj(
  nsim = 2, nn, ty, ex,
  logein = log(ein),
  logeout = log(sum(ex) - ein)
)

```

scan.stat

Spatial scan statistic

Description

scan.stat calculates the spatial scan statistic for a zone (a set of spatial regions). The statistic is the log of the likelihood ratio test statistic of the chosen distribution. If type = "poisson" and a is more than zero, this statistic is penalized. See references.

Usage

```

scan.stat(
  yin,
  ein = NULL,
  eout = NULL,
  ty,
  type = "poisson",
  popin = NULL,
  tpop = NULL,
  a = 0,
  shape = 1,
  yout = NULL,
  popout = NULL
)

```

```
stat.poisson(yin, yout, ein, eout, a = 0, shape = 1)
```

```
stat.binom(yin, yout, ty, popin, popout, tpop)
```

Arguments

yin	The total number of cases in the zone.
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be $ty - ein$ and is computed automatically if not provided.
ty	The total number of cases in the study area.

type	The type of scan statistic to implement. The default choice are "poisson". The other choice is "binomial".
popin	The total population in the zone.
tpop	The total population in the study area.
a	A tuning parameter for the adjusted log-likelihood ratio. See details.
shape	The shape of the ellipse, which is the ratio of the length of the longest and shortest axes of the ellipse. The default is 1, meaning it is a circle.
yout	The observed number of cases outside the zone. This should be $ty - yin$ and is computed automatically if not provided.
popout	The population outside the zone. This should be $tpop - popin$ and is computed automatically if not provided.

Value

A vector of scan statistics.

Examples

```
# New York leukemia data
# total cases
ty <- 552
# total population
tpop <- 1057673

# poisson example with yin = 106 and ein = 62.13
scan.stat(yin = 106, ty = ty, ein = 62.13)
stat.poisson(
  yin = 106, yout = 552 - 106,
  ein = 62.13, eout = 552 - 62.13
)

# binomial example with yin = 41 and popin = 38999
scan.stat(
  yin = 41, ty = ty,
```

```

    popin = 38999, tpop = tpop, type = "binomial"
  )
  stat.binom(41, ty - 41, ty, 38999, tpop - 38999, tpop)

```

 scan.test

Spatial Scan Test

Description

scan.test performs the original spatial scan test of Kulldorf (1997) based on a fixed number of cases. Candidate zones are circular and extend from the observed region centroids. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Usage

```

scan.test(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  longlat = FALSE,
  cl = NULL,
  type = "poisson",
  min.cases = 2,
  simdist = "multinomial"
)

```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
min.cases	The minimum number of cases required for a cluster. The default is 2.
simdist	Character string indicating the simulation distribution. The default is "multinomial", which conditions on the total number of cases observed. The other options are "poisson" and "binomial"

Value

Returns a `smerc_cluster` object.

}
# extract detected clusters
clusters(out)

# a second example to match the results of Waller and Gotway (2005)
# in chapter 7 of their book (pp. 220-221).
# Note that the 'longitude' and 'latitude' used by them has
# been switched. When giving their input to SatScan, the coords
# were given in the order 'longitude' and 'latitude'.
# However, the SatScan program takes coordinates in the order
# 'latitude' and 'longitude', so the results are slightly different
# from the example above.
# Note: the correct code below would use cbind(x, y), i.e.,
# cbind(longitude, latitude)
coords <- with(nydf, cbind(y, x))
out2 <- scan.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, nsim = 0,
  alpha = 1, longlat = TRUE
)
# the cases observed for the clusters in Waller and Gotway: 117, 47, 44
# the second set of results match
clusters(out2, idx = 1:3)

```

scan.zones

Determine zones for the spatial scan test

Description

scan.zones determines the unique candidate zones to consider for the circular spatial scan test of Kulldorff (1997).

Usage

```
scan.zones(coords, pop, ubpop = 0.5, longlat = FALSE)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.

Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

```

sig_noc

Return most significant, non-overlapping zones

Description

sig_noc return the significant, non-overlapping zones order from most significant to least significant.

Usage

```
sig_noc(tobs, zones, pvalue, alpha, order_by = "tobs")
```

Arguments

tobs	The vector of observed test statistics for each zone
zones	A list of zones

pvalue	The p-value associated with each test statistic
alpha	The significance level of the test.
order_by	Either 'tobs' or 'pvalue', indicating the argument by which to order zones.

Value

A list with the significant, ordered, non-overlapping tobs, zones, pvalue., and idx (a vector with the relevant indices of the original zones).

Examples

```
tobs <- c(1, 3, 2)
zones <- list(1:2, 1:3, 2:3)
pvalue <- c(0.5, 0.01, 0.02)
sig_noc(tobs, zones, pvalue, alpha = 0.05)
```

smerc	<i>smerc</i>
-------	--------------

Description

Statistical **ME**thods for **R**egional **C**ounts

Details

The ***smerc*** package implements statistical methods for analyzing the counts of areal data, with a focus on the detection of spatial clusters and clustering. The package has a heavy emphasis on spatial scan methods.

smmerc_cluster	<i>Prepare smmerc_cluster</i>
----------------	-------------------------------

Description

smmerc_cluster prepares a smmerc_cluster.

Usage

```
smmerc_cluster(
  tobs,
  zones,
  pvalue,
  coords,
  cases,
  pop,
  ex,
  longlat,
  method,
  rel_param,
  alpha,
  w = NULL,
  d = NULL,
  a = NULL,
  shape_all = NULL,
  angle_all = NULL,
  weights = NULL
)
```

Arguments

tobs	The vector of observed test statistics for each zone
zones	A list of zones
pvalue	The p-value associated with each test statistic
coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
method	A character string indicating the method used to construct the smmerc_cluster.

rel_param	A names list with the relevant parameters associated with method.
alpha	The significance level of the test.
w	A binary spatial adjacency matrix for the regions.
d	A precomputed distance matrix based on coords
a	A single value ≥ 0 indicating the penalty to use for elliptic.test .
shape_all	A vector of shape parameters associated with zones.
angle_all	A vector of angle parameter associated with zones.
weights	A vector of weights that multiply the cases, ex, and pop prior to computing summary statistics.

Value

A `smerc_cluster` object. The object generally has the following components:

clusters	A list containing information about the significant clusters. See further details below.
coords	The matrix of centroid coordinates.
number_of_regions	The number of regions considered.
total_population	The total population in the regions.
total_cases	The total number of cases in the regions.
cases_per_100k	The rate of cases per 100,000 persons.
method	The name of the method applied.
rel_param	A list of relevant method parameters.
alpha	The significance level.
longlat	A logical value indicating which type of distance was used.

Each element of the `clusters` component has:

locids	The ids of the regions in the cluster.
centroid	The cluster centroid.
r	The radius of the region (from the starting region to last region of the cluster).
max_dist	The maximum intercentroid distance between all the regions in the cluster.
population	The total population in the cluster.
cases	The number of cases in the cluster.
expected	The expected number of cases in the cluster.
smr	Standardized mortality ratio (cases/expected) in the cluster.
rr	Relative risk in the cluster window. This is $(\text{cases}/\text{pop}) / ((\text{total_cases} - \text{cases}) / (\text{total_population} - \text{population}))$.
loglikrat	The log of the likelihood ratio test statistic for the cluster. Only valid for the scan-type tests.

test_statistic The test statistic for the cluster.
 pvalue The p-value of the test statistic associated with the cluster.
 w The adjacency information for the cluster.

For `elliptic.test`, clusters additionally has:

semiminor_axis The semi-minor axis length for the ellipse.
 semimajor_axis The semi-major axis length for the ellipse.
 angle The rotation angle of the ellipse.
 shape The shape of the ellipse.

summary.smerc_cluster *Summary of smerc_cluster object*

Description

Summary of object of class `smerc_cluster`.

Usage

```
## S3 method for class 'smerc_cluster'
summary(object, ..., idx = seq_along(object$clusters), digits = 1)
```

Arguments

object An object of class `smerc_cluster`.
 ... Additional arguments affecting the summary produced.
 idx An index vector indicating the elements of `object$clusters` to print information for. The default is all clusters.
 digits Integer indicating the number of decimal places.

Value

A data.frame with columns:

nregions The number of regions in the cluster.
 max_dist The maximum intercentroid distance between all the regions in the cluster.
 cases The number of cases in the cluster.
 ex The expected number of cases in the cluster.
 rr Relative risk in the cluster window. This is $(\text{cases/pop}) / ((\text{total_cases} - \text{cases}) / (\text{total_population} - \text{population}))$.
 stat The test statistic for the cluster.
 p The p-value of the test statistic associated with the cluster.

Examples

```

data(nydf)
coords <- with(nydf, cbind(x, y))
out <- scan.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, nsim = 49,
  longlat = TRUE, alpha = 0.2
)
# summarize all clusters
summary(out)
# summarize clusters 1 and 3
summary(out, idx = c(1, 3))

```

tango.stat	<i>Tango's statistic</i>
------------	--------------------------

Description

tango.stat computes Tango's index (Tango, 1995), including both the goodness-of-fit and spatial autocorrelation components. See Waller and Gotway (2005).

Usage

```
tango.stat(cases, pop, w)
```

Arguments

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	An $n \times n$ weights matrix.

Value

Returns a list with the test statistic (tstat), the goodness-of-fit component (gof), and the spatial autocorrelation component (sa).

Author(s)

Joshua French

References

Tango, T. (1995) A class of tests for detecting "general" and "focused" clustering of rare diseases. *Statistics in Medicine*. 14:2323-2334.

Waller, L.A. and Gotway, C.A. (2005). *Applied Spatial Statistics for Public Health Data*. Hoboken, NJ: Wiley.

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
w <- dweights(coords, kappa = 1, type = "tango", longlat = TRUE)
tango.stat(nydf$cases, nydf$pop, w)
```

tango.test	<i>Tango's clustering detection test</i>
------------	--

Description

tango.test performs a test for clustering proposed by Tango (1995). The test uses Tango's chi-square approximation for significance testing by default, but also uses Monto Carlo simulation when `nsim > 0`.

Usage

```
tango.test(cases, pop, w, nsim = 0)
```

Arguments

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	An $n \times n$ weights matrix.
nsim	The number of simulations for which to perform a Monto Carlo test of significance. Counts are simulated according to a multinomial distribution with <code>sum(cases)</code> total cases and class probabilities <code>pop/sum(pop)</code> . <code>sum(cases)</code> .

Details

The `dweights` function can be used to construct a weights matrix `w` using the method of Tango (1995), Rogerson (1999), or a basic style.

Value

Returns a list of class `tango` with elements:

tstat	Tango's index
tstat.chisq	The approximately chi-squared statistic proposed by Tango that is derived from tstat
dfc	The degrees of freedom of tstat.chisq
pvalue.chisq	The p-value associated with tstat.chisq
tstat.sim	The vector of test statistics from the simulated data if <code>nsim > 0</code>
pvalue.sim	The p-value associated with the Monte Carlo test of significance when <code>nsim > 0</code>

Additionally, the goodness-of-fit `gof` and spatial autocorrelation `sa` components of the Tango's index are provided (and for the simulated data sets also, if appropriate).

[dweights](#)

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("x", "y")])
w <- dweights(coords, kappa = 1)
results <- tango.test(nydf$cases, nydf$pop, w, nsim = 49)
```

tango.weights

Distance-based weights for tango.test

Description

tango.weights constructs a distance-based weights matrix. The tango.weights function can be used to construct a weights matrix w using the method of Tango (1995), Rogerson (1999), or a basic style.

Usage

```
tango.weights(coords, kappa = 1, longlat = FALSE, type = "basic", pop = NULL)
```

```
dweights(coords, kappa = 1, longlat = FALSE, type = "basic", pop = NULL)
```

Arguments

- | | |
|---------|--|
| coords | An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance. |
| kappa | A positive constant related to strength of spatial autocorrelation. |
| longlat | The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance. |

type	The type of weights matrix to construct. Current options are "basic", "tango", and "rogerson". Default is "basic". See Details.
pop	The population size associated with each region.

Details

coords is used to construct an $n \times n$ distance matrix d .

If type = "basic", then $w_{ij} = \exp(-d_{ij}/\kappa)$.

If type = "rogerson", then $w_{ij} = \exp(-d_{ij}/\kappa) / \sqrt{(pop_i/pop * pop_j/pop)}$.

If type = "tango", then $w_{ij} = \exp(-4 * d_{ij}^2 / \kappa^2)$.

Value

Returns an $n \times n$ matrix of weights.

[tango.test](#)

Examples

```
data(nydf)
coords <- as.matrix(nydf[, c("longitude", "latitude")])
w <- tango.weights(coords, kappa = 1, longlat = TRUE)
```

uls.sim

Perform uls.test on simulated data

Description

uls.sim efficiently performs [uls.test](#) on a simulated data set. The function is meant to be used internally by the [uls.test](#) function, but is informative for better understanding the implementation of the test.

Usage

```
uls.sim(
  nsim = 1,
  ty,
  ex,
  w,
  pop,
  ubpop,
  type = "poisson",
  check.unique = FALSE,
  cl = NULL
)
```

Arguments

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>ty</code>	The total number of cases in the study area.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>pop</code>	The population size associated with each region.
<code>ubpop</code>	The upperbound of the proportion of the total population to consider for a cluster.
<code>type</code>	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
<code>check.unique</code>	A logical value indicating whether a check for unique values should be determined. The default is FALSE. This is unlikely to make a practical difference for most real data sets.
<code>cl</code>	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.

Value

A vector with the maximum test statistic for each simulated data set.

Examples

```
data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
pop <- nydf$pop
ty <- sum(cases)
ex <- ty / sum(pop) * pop
tsim <- uls.sim(1, ty, ex, nyw, pop = pop, ubpop = 0.5)
```

uls.test

*Upper Level Set Spatial Scan Test***Description**

uls.test performs the Upper Level Set (ULS) spatial scan test of Patil and Taillie (2004). The test is performed using the spatial scan test based on a fixed number of cases. The windows are based on the Upper Level Sets proposed by Patil and Taillie (2004). The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

Usage

```
uls.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  longlat = FALSE,
  cl = NULL,
  type = "poisson",
  check.unique = FALSE
)
```

Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions in the form (x, y) or (longitude, latitude) is using great circle distance.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance). It can also be "future" to use a future backend (see Details), NULL (default) refers to sequential evaluation.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
check.unique	A logical value indicating whether a check for unique values should be determined. The default is FALSE. This is unlikely to make a practical difference for most real data sets.

Details

The ULS method has a special (and time consuming) construction when the observed rates aren't unique. This is unlikely to arise for real data, except with observed rates of 0, which are of little interest. The method can take substantially if this is considered.

Value

Returns a list of length two of class `scan`. The first element (`clusters`) is a list containing the significant, non-overlapping clusters, and has the following components:

locids	The location ids of regions in a significant cluster.
pop	The total population in the cluster window.
cases	The observed number of cases in the cluster window.
expected	The expected number of cases in the cluster window.
smr	Standardized mortality ratio (observed/expected) in the cluster window.
rr	Relative risk in the cluster window.
loglikrat	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
pvalue	The pvalue of the test statistic associated with the cluster window.

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

Examples

```

data(nydf)
data(nyw)
coords <- with(nydf, cbind(longitude, latitude))
out <- uls.test(
  coords = coords, cases = floor(nydf$cases),
  pop = nydf$pop, w = nyw,
  alpha = 0.05, longlat = TRUE,
  nsim = 9, ubpop = 0.5
)
# better plotting
if (require("sf", quietly = TRUE)) {
  data(nysf)
  plot(st_geometry(nysf), col = color.clusters(out))
}

```

uls.zones

*Determine sequence of ULS zones.***Description**

uls.zones determines the unique zones obtained by implementing the ULS (Upper Level Set) test of Patil and Taillie (2004).

Usage

```
uls.zones(cases, pop, w, ubpop = 0.5, check.unique = FALSE)
```

Arguments

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
check.unique	A logical value indicating whether a check for unique values should be determined. The default is FALSE. This is unlikely to make a practical difference for most real data sets.

Details

The zones returned must have a total population less than $ubpop * \text{sum}(\text{pop})$ of all regions in the study area.

Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

```

zones.sum	<i>Sum over zones</i>
-----------	-----------------------

Description

zones.sum computes the sum of y for the indices in each element of the list contained in zones.

Usage

```
zones.sum(zones, y)
```

Arguments

zones A list of nearest neighbors in the format produced by [scan.zones](#).
y A numeric vector of values to be summed over.

Value

A numeric vector.

Examples

```
# show nn.cumsum example for a circular scan setting
data(nydf)
coords <- with(nydf, cbind(longitude, latitude))
cases <- floor(nydf$cases)
zones <- scan.zones(coords, pop = nydf$pop, ubpop = 0.1)
# compute cumulative sums over all nn
szones <- zones.sum(zones, cases)
# compute cumulative sums over just the first set of nn
szones2 <- sapply(zones, function(x) sum(cases[x]))
# check equality
all.equal(szones, zones2)
```
